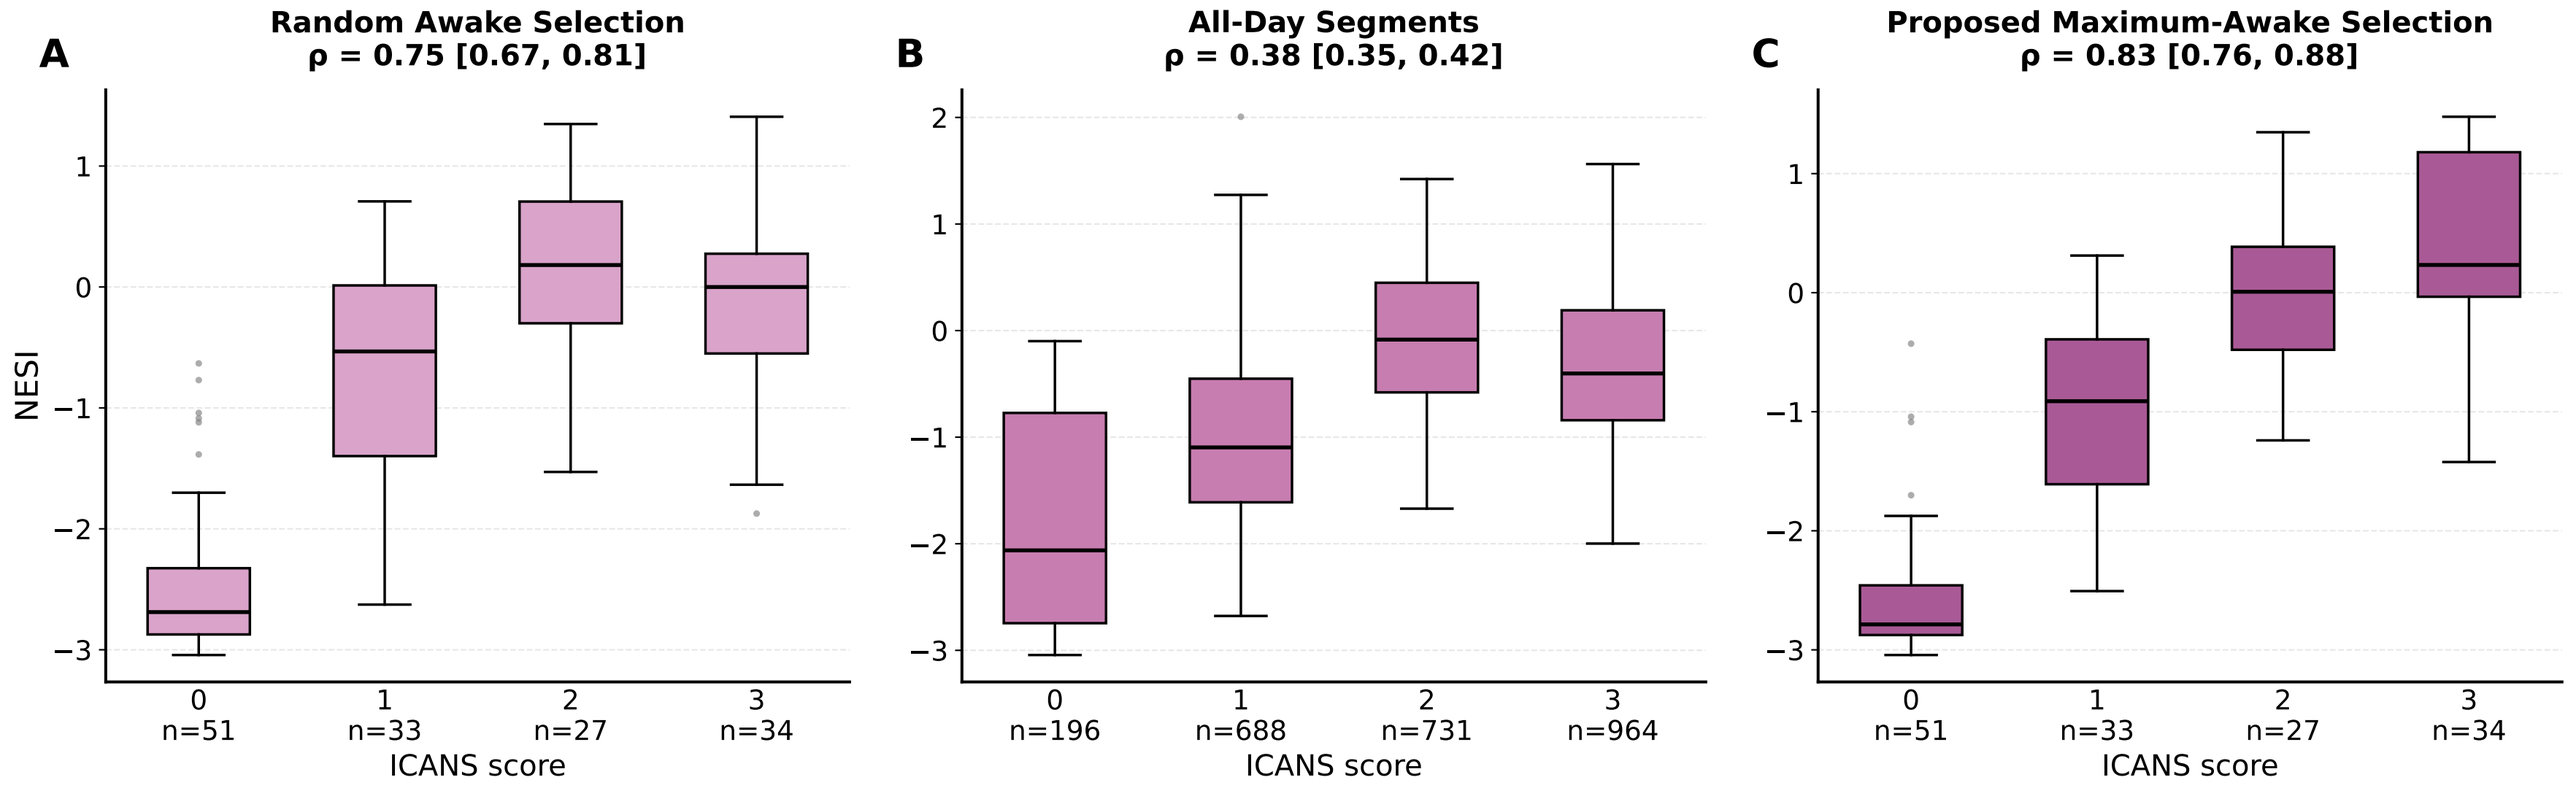
ICANS Ablation Study: Effect of EEG Segment Selection on NESI

A: Random selection of awake EEG segments | B: All-day EEG segments irrespective of vigilance state | C: Proposed selection of maximally awake EEG segments



Boxes: median and IQR; whiskers: 1.5×IQR; gray points: outliers.

n denotes the number of EEG observations at each ICANS grade. Higher NESI values indicate more severe neurological dysfunction.

Spearman's ρ and 95% CIs were estimated using 1,000 observation-level bootstrap iterations.
